

WP2.1 The role of microbial peat decomposition in land subsidence

Duygu Tolunay, MSc

Ecology & Biodiversity, Institute of Environmental Biology, Utrecht University 3584 CH Utrecht, Padualaan 8, Hugo R. Kruytgebouw, Room N307

<u>d.tolunay@uu.nl</u>

Research Focus

- Revealing the contribution of water-saturated peat layers to land subsidence in terms of microbial activity
- Understanding the drivers of microbial decomposition in peatlands
- Determining the environmental factors that effects the microbial decomposition rate

Bunschoten Sphagnum

Short-term and mid-range disturbance effects on the anoxic microbial decomposition

- Anoxic sample collection from botanically different peatlands
- Anoxic and oxic incubation at the laboratory for three months
- Monitoring microbial activity by checking CO₂ production and enzyme activities
- Collecting information about organic matter content, pH, the concentration of phenolic compounds

PRELIMENARY RESULTS

Zegveld Wood

- \geq Oxygen exposure increases the microbial CO₂ production from different peatlands at different rate
- > Hydrolytic exoenyzmes are positively correlated with each other but there is not strong correlation with microbial basal respiration rate.
- > pH plays a critical role in the microbial respiration rate.
- > Phenol oxidase gets active with the oxygen presence, but Imid-range oxygen exposure decrease the activity due to the depletion of
- available substrate for the enzyme or/and due to pH changes
- > Soluble phenolics increased in Zegveld peat and decreased in Rouveen peat the most.

MAIN CONCLUSIONS

- > Available energy sources might be the main driver of the microbial activity in peatlands
- > Different peatlands show different behaviour in terms of microbial activity. Therefore, local drivers should be revealed for an effective management strategies
- > Anaerobic microbial activity might be important for land subsidence, therefore the future models should consider the rate of anaerobic

Changes in soluble phenolics between four peatlands

NEXT STEPS

Cross experiment to determine whether microbial decomposition rate is determined by the community or the available energy source in the peat

Field experiment: Transferring water saturated peat layers to oxygen rich layers and the other way around to monitor the effects of peat history on microbial decomposition.

Determine potential energy source for microbial community under water saturated conditions Check the effects of Iron and sulfate presence on microbial decomposition Reveal the contribution of anaerobic decomposition to the land subsidence rate

The relationship between microbial decomposition and physical land subsidence processes

"The research presented in this paper is part of the project Living on soft soils: subsidence and society (grantnr.: NWA.1160.18.259). This project is funded by the Dutch Research Council (NWO-NWA-ORC), Utrecht University, Wageningen University, Delft University of Technology, Ministry of Infrastructure & Water Management, Ministry of the Interior & Kingdom Relations, Deltares, Wageningen Environmental Research, TNO-Geological Survey of The Netherlands, STOWA, Water Authority: Hoogheemraadschap de Stichtse Rijnlanden, Water Authority: Drents Overijsselse Delta, Province of Utrecht, Province of Zuid-Holland, Municipality of Gouda, Platform Soft Soil, Sweco, Tauw BV, NAM."
